A Guide to Heat Treatment and Metal Properties - Bright Hub Engineering. This article describes the need for heat treatment. The various heat treatment processes such as annealing, carburizing, case hardening, induction hardening, nitriding, cementation, tempering, etc. are explained in detail. The basics of hardness measurement, units of hardness measurement such as Rockwell hardness, Brinell hardness, etc. are explained in different articles.

The heat-treat process results in unavoidable size increases in tool steels because of the changes in their microstructure. Most tool steels grow between about 0.0005 and 0.002 inch per inch of original length during heat treatment. This varies somewhat based on a number of theoretical and practical factors.

The purpose of heat treating is to bring steel to a hardened state. The correct hardness depends on the application of the steel being treated. Knives need to be hard enough to hold an sharp edge through continuous mechanical abrasion, yet be soft (flexible) enough to stand up to forceful use without breaking.

Annealing is the softening of metal by heat treatment. Ferrous metals are annealed by heating to just above the A3 point (a point above non-magnetic that varies with the carbon content), and then cooling slowly. For common carbon steels the cooling can be done in dry ashes, lime powder or vermiculite.
